
Subject: Ilfx woes

Posted by [Nat Hall](#) on Mon, 28 Mar 2022 00:03:18 GMT

[View Forum Message](#) <> [Reply to Message](#)

Hi all,

Been probably 15 years since I posted here.

After moving last summer, I set up my long dormant/closeted Ilfx that had been out of circulation for at least 10 years. To my surprise, it booted right up into OS 8.1 and my second hard drive with A/UX booted right up as well.

It was a blast from the past to see my most recent Low End Mac usergroup emails, the most recent of which was June 2006. A moment frozen in time.

I started a new A/UX project on it and after about 4 months, it just died a sudden, hopefully NOT ugly death.

I went to power down one evening and instead of shutting off, the video display corrupted and just sat there. I had to unplug the power cable.

When I went to start up the next day, I get the normal startup bong, the hard drives spin up normally, then I get the do-do-da-da and the screen just sits on the all-grey screen with the "radius" logo at the bottom.

Since then, I have:

- swapped RAM, tried many different configurations
- tried a different video card (only difference here is the blank grey screen doesn't get the "radius" logo, since it's an apple card)
- removed all nubus cards
- removed all hard drives
- removed floppy drives
- removed all external peripherals
- tried a host of different keyboard/mouse configurations
- thoroughly cleaned the logic board (it looks brand new, excellent condition)
- tried holding the ROM SIMM at various angles, I've read these slots can be touchy
- installed fresh PRAM batteries
- zapped PRAM
- tried different SCSI cables and configurations

Nothing has any effect at all, the exact same scenario plays out in all cases. The only thing aside from the lack of "radius" logo with the Apple card is there is a longer/shorter delay between the startup bong and the do-do-da-da that is directly correlated with how much RAM I have installed, which leads me to believe whatever is happening is happening after the RAM check.

My next thought is to try to hunt down a replacement ROM, but I thought I'd check in here first, see if anyone has any other thoughts. I tried the Dead Mac Scrolls, my exact scenario isn't listed

but it's closest to what is described on pages 225 and 226, although the drives/termination on the SCSI bus on this machine haven't changed in 22 years. Also, the do-do-da-da does not come quickly after the bong, it comes after 15-30 seconds after the RAM check.

The first thing to do is have the capacitors replaced. There's no point to other troubleshooting until that is taken care of.

Aren't most of the capacitors on the Ilfx logicboard Tantalums rather than electrolytics?

There are some electrolytic on the Ilfx board. Don't overlook failing capacitors in the power supply. Marginal power can allow it to turn on but not have quite enough power to run the RAM,

accessories, etc. I would look at recapping the PSU.

Yep, what Dylan said. The Ilfx shipped with varying combinations of tantalum/electrolytic capacitors. Have to treat each machine individually. Plus the PSU. Some people replace the old PSUs with new ATX ones. That's another option. My preference is to extend the life of the original parts as much as possible.
